

Releases that **undo** themselves

when the new version is bad, in under a minute

Normal release

100%

of users hit the bug

3 AM

This project

~20%

for ~47 s, then auto-undo

sleep

THE PROBLEM

How most teams release 📌

1 · Deploy

✓ **"Success"**

to everyone, all at once

2 · Hidden bug

100% of users

3 · Alarm

3:00 AM

"is it bad enough to undo?"

4 · Manual undo

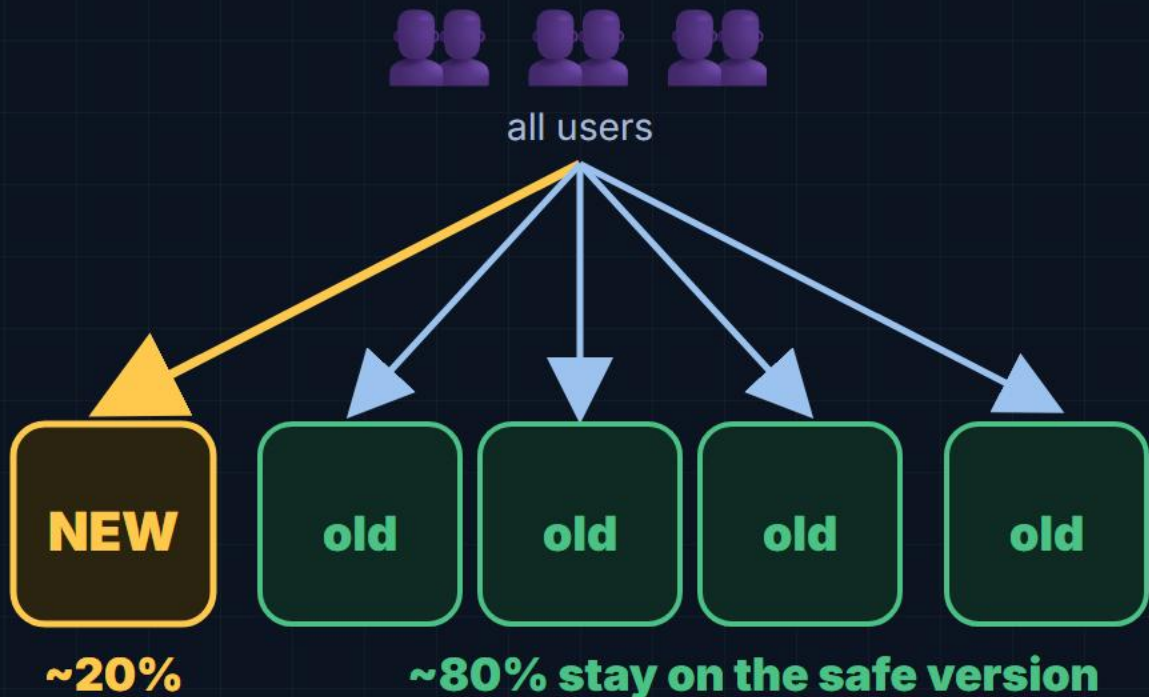

slow & stressful

every minute = more angry users

THE IDEA

Try the new version on a **few users** first

Every 30 s, check the NEW one:

✗ failing requests

🕒 response time

WHEN TO USE IT

A good fit when...

You release often

weekly · daily · hourly

Real customers

shops · payments · apps

Someone is on call

fewer 3 AM decisions

You run Kubernetes

and have (or want) metrics

X Skip it when

a tiny tool has almost no traffic, or you release twice a year

HOW A TEAM USES IT

Release as usual. **The system decides.**

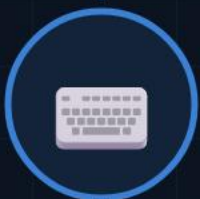

Set a target

"99.5% of requests succeed"

The app reports numbers

errors & speed, every 5 s

Ship with one command

`helm upgrade --set image.tag=1.2.0`

It rolls out step by step

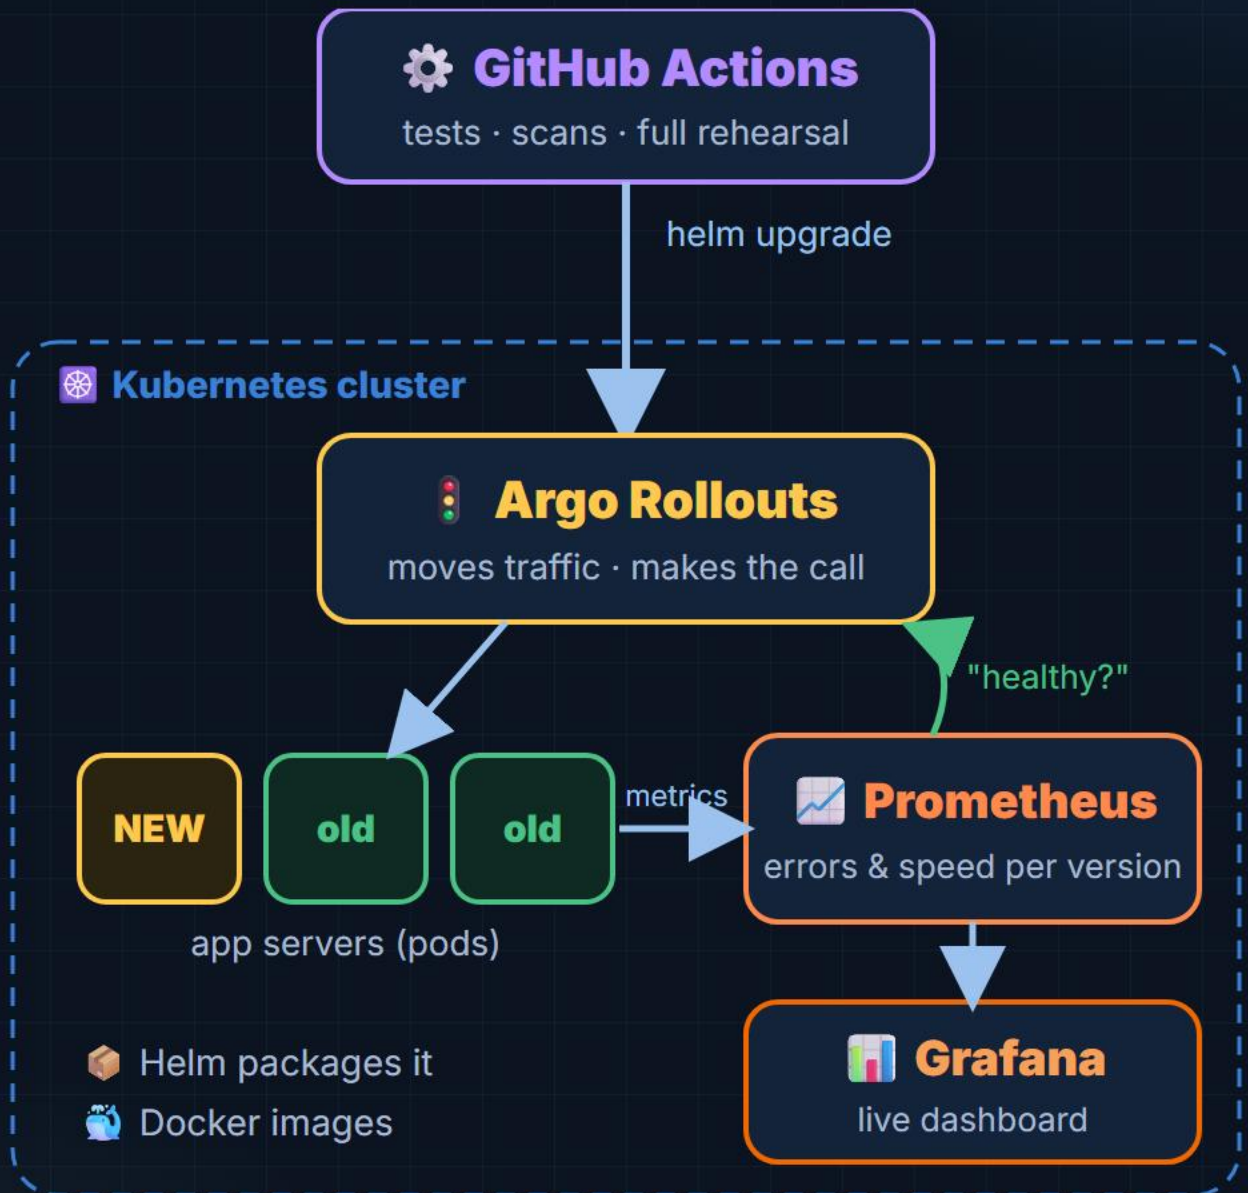

20 → 40 → 60 → 80 → 100%

Promoted or undone

automatically, nobody woken up

How the pieces connect

Two dials decide every 30 s

**✗ Failed requests
must stay $\leq 7.2\%$**

**🕒 Speed (p95)
must stay ≤ 300 ms**

next step $\rightarrow 100\%$

2x red $\rightarrow$ undo

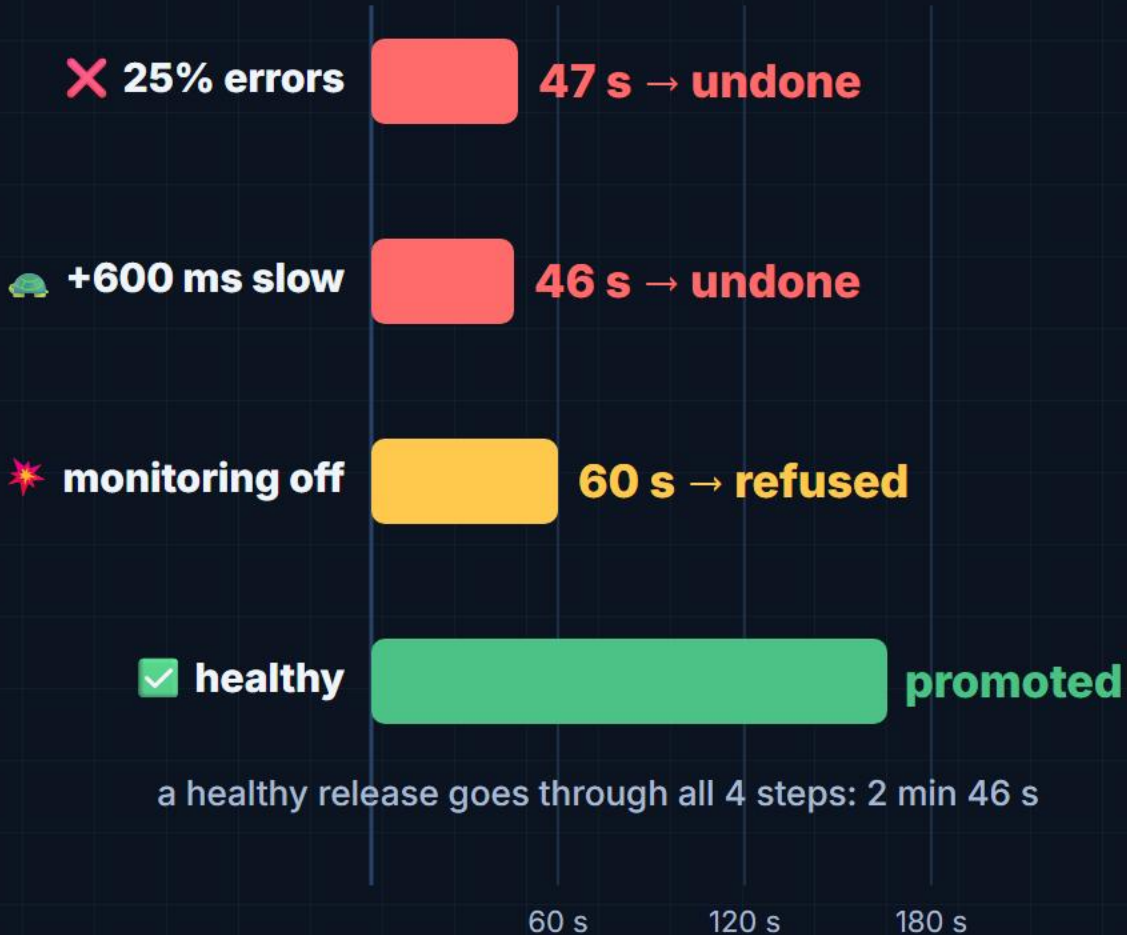

Can't measure? $\rightarrow$ undo

no traffic or monitoring down = no promotion

DOES IT WORK? TESTED ✓

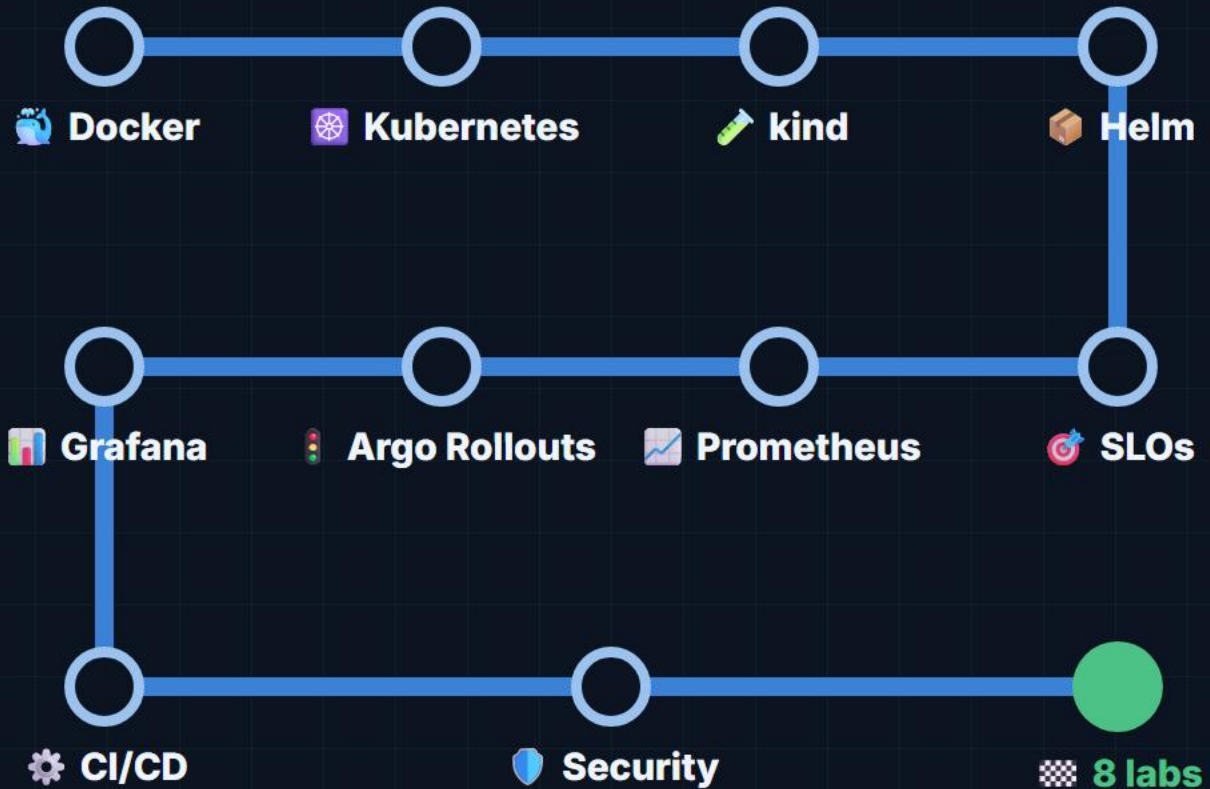

Seconds from release to decision

Lab results · local kind cluster + GitHub Actions · not production traffic

TRY IT YOURSELF

On your laptop in ~3 minutes

```
$ git clone ...slo-progressive-delivery
```

① **get it**

```
$ make up
```

② **build all**

```
$ scripts/release.sh 1.1.0
```

③

④ **undo**

```
$ release.sh 1.2.0 --inject-errors
```

⑤ **live**

```
$ open the dashboard 
```

needs only free tools: Docker · kind · kubectl · helm
